

**Problem 1.**

Determine the behaviour of the following sequences.

(a)  $u_n = 3 \left( \frac{1}{2} \right)^{n-1}$

(b)  $v_n = 2 - n$

(c)  $t_n = (-1)^n$

(d)  $w_n = 4$

**Solution**

**Part (a)**

Decreasing, converges to 0.

**Part (b)**

Decreasing, diverges.

**Part (c)**

Alternating, diverges.

**Part (d)**

Constant, converges to 4.

**Problem 2.**

Find the sum of all even numbers from 20 to 100 inclusive.

**Solution**

$$\begin{aligned}\sum_{n=10}^{50} 2n &= 2 \left( \sum_{n=1}^{50} n - \sum_{n=1}^9 n \right) \\ &= 2 \left( \frac{50 \cdot 51}{2} - \frac{9 \cdot 10}{2} \right) \\ &= 2460\end{aligned}$$

The sum of all even numbers from 20 to 100 inclusive is 2460.

**Problem 3.**

A geometric series has first term 3, last term 384 and sum 765. Find the common ratio.

**Solution**

Let the  $n$ th term of the geometric series be  $ar^{n-1}$ , where  $1 \leq n \leq k$ . We hence have  $3r^{k-1} = 384$ , which gives  $r^k = 128r$ .

Next, we know that  $\frac{3(1-r^k)}{1-r} = 765$ . Thus,

$$\begin{aligned} & \frac{3(1-128r)}{1-r} = 765 \\ \implies & \frac{1-128r}{1-r} = 255 \\ \implies & 1-128r = 255-255r \\ \implies & 127r = 254 \\ \implies & r = 2 \end{aligned}$$

The common ratio is 2.

**Problem 4.**

- (a) Find the first four terms of the following sequence  $u_{n+1} = \frac{u_n + 1}{u_n + 2}$ ,  $u_1 = 0$ ,  $n \geq 1$ .
- (b) Write down the recurrence relation between the terms of these sequences.
- (i)  $-1, 2, -4, 8, -16, \dots$
- (ii)  $1, 3, 7, 15, 31, \dots$

**Solution****Part (a)**

$$\begin{aligned}u_1 &= 0 \\ \Rightarrow u_2 &= \frac{u_1 + 1}{u_1 + 2} = \frac{1}{2} \\ \Rightarrow u_3 &= \frac{u_2 + 1}{u_2 + 2} = \frac{3}{5} \\ \Rightarrow u_4 &= \frac{u_3 + 1}{u_3 + 2} = \frac{8}{13}\end{aligned}$$

The first four terms of the sequence are  $0, \frac{1}{2}, \frac{3}{5}$  and  $\frac{8}{13}$ .

**Part (b)****Subpart (i)**

$$u_{n+1} = -2u_n, u_1 = -1, n \geq 1$$

**Subpart (ii)**

$$u_{n+1} = 2u_n + 1, u_1 = 1, n \geq 1$$

**Problem 5.**

The sum of the first  $n$  terms of a series,  $S_n$ , is given by  $S_n = 2n(n + 5)$ . Find the  $n$ th term and show that the terms are in arithmetic progression.

**Solution**

$$\begin{aligned} S_n &= 2n(n + 5) \\ &= 4 \cdot \frac{n(n + 1)}{2} + 8n \\ &= 4 \sum_{k=1}^n k + 8 \sum_{k=1}^n 1 \\ &= \sum_{k=1}^n (4k + 8) \end{aligned}$$

$$\boxed{u_n = 4n + 8}$$

**Test for Arithmetic Progression.**

$$\begin{aligned} u_{n+1} - u_n &= 4(n + 1) + 8 - (4n + 8) \\ &= 4 \end{aligned}$$

**Problem 6.**

The sum of the first  $n$  terms,  $S_n$ , is given by

$$S_n = \frac{1}{2} - \left(\frac{1}{2}\right)^{n+1}$$

- (a) Find an expression for the  $n$ th term of the series.
- (b) Hence or otherwise, show that it is a geometric series.
- (c) State the values of the first term and the common ratio.
- (d) Give a reason why the sum of the series converges as  $n$  approaches infinity and write down its value.

**Solution****Part (a)**

$$\begin{aligned} u_n &= S_n - S_{n-1} \\ &= \frac{1}{2} - \left(\frac{1}{2}\right)^{n+1} - \left(\frac{1}{2} - \left(\frac{1}{2}\right)^n\right) \\ &= \left(\frac{1}{2}\right)^n - \left(\frac{1}{2}\right)^{n+1} \\ &= \left(\frac{1}{2}\right)^n \left(1 - \frac{1}{2}\right) \\ &= \frac{1}{2} \cdot \left(\frac{1}{2}\right)^n \\ &= \left(\frac{1}{2}\right)^{n+1} \end{aligned}$$

$$\boxed{u_n = \left(\frac{1}{2}\right)^{n+1}}$$

**Part (b)**

**Test for Geometric Progression.**

$$\begin{aligned} \frac{u_{n+1}}{u_n} &= \left(\frac{1}{2}\right)^{n+2} \bigg/ \left(\frac{1}{2}\right)^{n+1} \\ &= \frac{1}{2} \end{aligned}$$

**Part (c)**

$$\boxed{\text{The first term is } \frac{1}{4} \text{ and the common ratio is } \frac{1}{2}.$$

**Part (d)**

Consider  $\lim_{n \rightarrow \infty} S_n = \lim_{n \rightarrow \infty} \frac{1}{2} - \left(\frac{1}{2}\right)^{n+1}$ . As  $n \rightarrow \infty$ , we see that  $\left(\frac{1}{2}\right)^{n+1} \rightarrow 0$ .

Hence,  $S_n$  converges to  $\frac{1}{2}$ .

**Problem 7.**

The first term of an arithmetic series is  $\ln x$  and the  $r$ th term is  $\ln(xk^{r-1})$ , where  $k$  is a real constant. Show that the sum of the first  $n$  terms of the series is  $S_n = \frac{n}{2} \ln(x^2 k^{n-1})$ . If  $k = 1$  and  $x \neq 1$ , find the sum of the series  $e^{S_1} + e^{S_2} + e^{S_3} + \dots + e^{S_n}$ .

**Solution**

Let  $u_n$  be the  $n$ th term in the arithmetic series.

$$\begin{aligned} u_r &= \ln(xk^{r-1}) \\ &= \ln x + \ln k^{r-1} \\ &= \ln x + (r-1) \ln k \end{aligned}$$

Thus, we see that the arithmetic series has a common difference of  $\ln k$ .

$$\begin{aligned} \sum_{r=1}^n u_r &= \sum_{r=1}^n (\ln x + (r-1) \ln k) \\ &= n \ln x + \ln k \sum_{r=1}^n (r-1) \\ &= n \ln x + \ln k \left( \frac{n(n-1)}{2} \right) \\ &= \frac{n}{2} (2 \ln x + (n-1) \ln k) \\ &= \frac{n}{2} (\ln x^2 + \ln k^{n-1}) \\ &= \frac{n}{2} \ln(x^2 k^{n-1}) \end{aligned}$$

Consider  $e^{S_n}$  when  $k = 1$  and  $x \neq 1$ .

$$\begin{aligned} e^{S_n} &= e^{\frac{n}{2} \ln x^2} \\ &= e^{\ln(x^n)} \\ &= x^n \end{aligned}$$

Hence,

$$\begin{aligned} e^{S_1} + e^{S_2} + e^{S_3} + \dots + e^{S_n} &= x + x^2 + x^3 + \dots + x^n \\ &= \frac{x(1 - x^{n+1})}{1 - x} \end{aligned}$$

$$e^{S_1} + e^{S_2} + e^{S_3} + \dots + e^{S_n} = \frac{x(1 - x^{n+1})}{1 - x}$$

**Problem 8.**

A baker wants to bake a 1-metre tall birthday cake. It comprises 10 cylindrical cakes each of equal height 10 cm. The diameter of the cake at the lowest layer is 30 cm. The diameter of each subsequent layer is 4% less than the diameter of the cake below. Find the volume of this cake in  $\text{cm}^3$ , giving your answer to the nearest integer.

**Solution**

Let  $d_1, d_2, \dots, d_{10}$  be the diameters of each cylindrical cake such that  $d_{n+1} = \frac{96}{100}d_n$  and  $d_1 = 30$ . We thus have the closed form  $d_n = 30 \left( \frac{96}{100} \right)^{n-1}$ . Let the cake have a volume of  $V \text{ cm}^3$ . Then,

$$\begin{aligned}
 V &= \sum_{n=1}^{10} 10\pi \left( \frac{d_n}{2} \right)^2 \\
 &= \frac{5\pi}{2} \sum_{n=1}^{10} d_n^2 \\
 &= \frac{5\pi}{2} \sum_{n=1}^{10} \left( 30 \left( \frac{96}{100} \right)^{n-1} \right)^2 \\
 &= 2250\pi \sum_{n=1}^{10} \left( \frac{96}{100} \right)^{2n-2} \\
 &= 2250\pi \left( \frac{96}{100} \right)^{-2} \sum_{n=1}^{10} \left( \left( \frac{96}{100} \right)^2 \right)^n \\
 &= 2250\pi \left( \frac{96}{100} \right)^{-2} \frac{\left( \frac{96}{100} \right)^2 \left( 1 - \left( \left( \frac{96}{100} \right)^2 \right)^{10} \right)}{1 - \left( \frac{96}{100} \right)^2} \\
 &= 50309
 \end{aligned}$$

The cake has a volume of 50309  $\text{cm}^3$ .

## Problem 9.

The sum to infinity of a geometric progression is 5 and the sum to infinity of another series is formed by taking the first, fourth, seventh, tenth, ... terms is 4. Find the exact common ratio of the series.

### Solution

Let the  $n$ th term of the geometric progression be given by  $ar^{n-1}$ . Then, we have

$$\frac{a}{1-r} = 5 \quad (9.1)$$

Taking the first, fourth, seventh, tenth, ... terms, we get a new geometric series

$$a, ar^3, ar^6, ar^9, \dots$$

which has common ratio  $r^3$ . Thus,

$$\frac{a}{1-r^3} = 4 \quad (9.2)$$

Putting Equations 9.1 and 9.2 together, we have

$$\begin{aligned} 5(1-r) &= 4(1-r^3) \\ \implies 5-5r &= 4-4r^3 \\ \implies 4r^3-5r+1 &= 0 \\ \implies (r-1)(4r^2+4r-1) &= 0 \end{aligned}$$

We hence see that  $r = 1$  or  $4r^2 + 4r - 1 = 0$ . We reject  $r = 1$  since  $|r| < 1$ . Now consider  $4r^2 + 4r - 1 = 0$ . By the quadratic formula, we have  $r = \frac{-1 + \sqrt{2}}{2}$  or  $r = \frac{-1 - \sqrt{2}}{2}$ . Once again, since  $|r| < 1$ , we reject  $r = \frac{-1 - \sqrt{2}}{2}$ . Hence,  $r = \frac{-1 + \sqrt{2}}{2}$ .

The common ratio is $\frac{-1 + \sqrt{2}}{2}$ .
---

**Problem 10.**

A geometric series has common ratio  $r$ , and an arithmetic series has first term  $a$  and common difference  $d$ , where  $a$  and  $d$  are non-zero. The first three terms of the geometric series are equal to the first, fourth and sixth terms respectively of the arithmetic series.

- (a) Show that  $3r^2 - 5r + 2 = 0$
- (b) Deduce that the geometric series is convergent and find, in terms of  $a$ , the sum of infinity.
- (c) The sum of the first  $n$  terms of the arithmetic series is denoted by  $S$ . Given that  $a > 0$ , find the set of possible values of  $n$  for which  $S$  exceeds  $4a$ .

**Solution****Part (a)**

Let the  $n$ th term of the geometric series be  $G_n = G_1 r^{n-1}$ . Let the  $n$ th term of the arithmetic series be  $A_n = a + (n-1)d$ . Since  $G_1 = A_1$ , we have  $G_1 = a$ . We can thus re-express  $G_n$  as  $ar^{n-1}$ .

From  $G_2 = A_4$ , we have  $ar = a + 3d$ , which gives  $a = \frac{3d}{r-1}$ . From  $G_3 = A_6$ , we have  $ar^2 = a + 5d$ . We thus have

$$\begin{aligned}
 ar^2 - ar &= 2d \\
 \implies ar(r-1) &= 2d \\
 \implies \frac{3d}{r-1} r(r-1) &= 2d \\
 \implies 3dr &= 2d \\
 \implies r &= \frac{2}{3}
 \end{aligned}$$

It is thus obvious that  $3r^2 - 5r + 2 = 0$ .

**Part (b)**

Let  $S$  be the sum to infinity of  $G_n$ .

$$\begin{aligned}
 S &= \frac{a}{1-r} \\
 &= 3a
 \end{aligned}$$

The sum of the geometric series converges to  $3a$ .

**Part (c)**

$$\begin{aligned}
S &= \frac{n}{2}(2a + (n-1)d) \\
&= an + \frac{n(n-1)d}{2} \\
&= an + \frac{dn^2 - dn}{2}
\end{aligned}$$

Consider  $S > 4a$ .

$$\begin{aligned}
&S > 4a \\
\implies an + \frac{dn^2 - dn}{2} &> 4a \\
\implies 2an + dn^2 - dn &> 8a \\
\implies dn^2 + (2a - d)n - 8a &> 0
\end{aligned}$$

Note that  $a = \frac{3d}{r-1}$ , whence  $d = -\frac{a}{9}$ .

$$\begin{aligned}
\implies -\frac{a}{9}n^2 + (2a + \frac{a}{9})n - 8a &> 0 \\
\implies -\frac{1}{9}n^2 + (2 + \frac{1}{9})n - 8 &> 0 \\
\implies -n^2 + 19n - 72 &> 0
\end{aligned}$$

Observe that  $-n^2 + 19n - 72 = 0$  when  $n = 5.23$  or  $n = 13.8$ . Since the curve of  $-n^2 + 19n - 72$  is concave downwards, we have  $5.23 < n < 13.8$ . Since  $n$  is an integer,  $n$  must be between 6 and 13 inclusive.

$$\boxed{\{n \in \mathbb{Z}: 6 \leq n \leq 13\}}$$

**Problem 11.**

Two musical instruments,  $A$  and  $B$ , consist of metal bars of decreasing lengths.

- (a) The first bar of instrument  $A$  has length 20 cm and the lengths of the bars form a geometric progression. The 25th bar has length 5 cm. Show that the total length of all the bars must be less than 357 cm, no matter how many bars there are.

Instrument  $B$  consists of only 25 bars which are identical to the first 25 bars of instrument  $A$ .

- (b) Find the total length,  $L$  cm, of all the bars of instrument  $B$  and the length of the 13th bar.
- (c) Unfortunately, the manufacturer misunderstands the instructions and constructs instrument  $B$  wrongly, so that the lengths of the bars are in arithmetic progression with a common difference  $d$  cm. If the total length of the 25 bars is still  $L$  cm and the length of the 25th bar is still 5 cm, find the value of  $d$  and the length of the longest bar.

**Solution****Part (a)**

Let  $u_n = u_1 r^{n-1}$  be the length of the  $n$ th bar. Since  $u_1 = 20$ , we have  $u_n = 20r^{n-1}$ . Since  $u_{25} = 5$ , we have  $r = 4^{-\frac{1}{24}}$ . Hence,  $u_n = 20 \cdot 4^{-\frac{n-1}{24}}$ . Now, consider the sum to infinity of  $u_n$ .

$$\begin{aligned} \sum_{n=1}^{\infty} u_n &= \frac{u_1}{1-r} \\ &= \frac{20}{1-4^{-\frac{1}{24}}} \\ &= 356.34 \\ &< 357 \end{aligned}$$

Hence, no matter how many bars there are, the total length of the bars will never exceed 357 cm.

**Part (b)**

$$\begin{aligned} L &= \sum_{n=1}^{25} u_n \\ &= \frac{u_1(1-r^{25})}{1-r} \\ &= \frac{20(1-4^{-\frac{25}{24}})}{1-4^{-\frac{1}{24}}} \\ &= 272.26 \end{aligned}$$

$$L = 272 \text{ (3 s.f.)}$$

$$\begin{aligned} u_{13} &= 20 \cdot 4^{-\frac{13-1}{24}} \\ &= 10 \end{aligned}$$

The 13th bar is 10 cm long.

**Part (c)**

Let  $v_n = a + (n - 1)d$  be the length of the wrongly-manufactured bars. Since the length of the 25th bar is still 5 cm, we know  $v_{25} = a + 24d = 5$ . Now, consider the total lengths of the bars, which is still  $L$  cm.

$$\begin{aligned} L &= \sum_{n=1}^{25} v_n \\ &= \frac{25}{2}(a + 5) \\ &= 272.26 \end{aligned}$$

Rearranging, we have  $a = 16.781$ . Hence,  $d = \frac{5 - a}{24} = -0.491$ .

The longest bar is 16.8 cm long. The common difference  $d$  is  $-0.491$  cm.

**Problem 12.**

A bank has an account for investors. Interest is added to the account at the end of each year at a fixed rate of 5% of the amount in the account at the beginning of that year. A man and a woman both invest money.

- (a) The man decides to invest  $\$x$  at the beginning of one year and then a further  $\$x$  at the beginning of the second and each subsequent year. He also decides that he will not draw any money out of the account, but just leave it, and any interest, to build up.
- (i) How much will there be in the account at the end of 1 year, including the interest?
  - (ii) Show that, at the end of  $n$  years, when the interest for the last year has been added, he will have a total of  $\$21(1.05^n - 1)x$  in his account.
  - (iii) After how many complete years will he have, for the first time, at least  $\$12x$  in his account?
- (b) The woman decides that, to assist her in her everyday expenses, she will withdraw the interest as soon as it has been added. She invests  $\$y$  at the beginning of each year. Show that, at the end of  $n$  years, she will have received a total of  $\$ \frac{1}{40}n(n+1)y$  in interest.

**Solution****Part (a)****Subpart (i)**

There will be  $\$1.05x$  in the account at the end of 1 year.

**Subpart (ii)**

Let  $\$u_n x$  be the amount of money in the account at the end of  $n$  years. Then,  $u_n$  satisfies the recurrence relation  $u_{n+1} = 1.05(1 + u_n)$ , with  $u_1 = 1.05$ . Observe the following pattern.

$$\begin{aligned} u_1 &= 1.05 \\ \implies u_2 &= 1.05(1 + 1.05) = 1.05 + 1.05^2 \\ \implies u_3 &= 1.05(1 + 1.05 + 1.05^2) = 1.05 + 1.05^2 + 1.05^3 \end{aligned}$$

It thus stands to reason that  $u_n = \sum_{k=1}^n 1.05^k$ . Thus,  $u_n = \frac{1.05(1.05^n - 1)}{1.05 - 1} = 21(1.05^n - 1)$ . Hence, there is  $\$21(1.05^n - 1)x$  in the account after  $n$  years.

**Subpart (iii)**

Consider the inequality  $u_n \geq 12x$ .

$$\begin{aligned}
 & u_n x \geq 12x \\
 \implies & 21(1.05^n - 1) \geq 12 \\
 \implies & 1.05^n - 1 \geq \frac{12}{21} \\
 \implies & 1.05^n \geq \frac{33}{21} \\
 \implies & n \geq \log_{1.05} \frac{33}{21} \\
 \implies & n \geq 9.26
 \end{aligned}$$

Since  $n$  is an integer, the smallest value of  $n$  is 10.

After 10 years, he will have at least \$12x in his account for the first time.

### Part (b)

After  $n$  years, the woman will have  $\$ny$  in her account. Hence, the interest she gains after  $n$  years is  $0.05ny$ . Hence, the total interest she will gain is  $\sum_{k=1}^n \frac{1}{20}ny = \frac{1}{20} \cdot \frac{n(n+1)}{2} \cdot y = \frac{1}{40}n(n+1)y$ .

**Problem 13.**

The sum,  $S_n$ , of the first  $n$  terms of a sequence  $U_1, U_2, U_3, \dots$  is given by

$$S_n = \frac{n}{2}(c - 7n)$$

where  $c$  is a constant.

- (a) Find  $U_n$  in terms of  $c$  and  $n$ .
- (b) Find a recurrence relation of the form  $U_{n+1} = f(U_n)$ .

**Solution****Part (a)**

$$\begin{aligned} S_n &= \frac{n}{2}(c - 7n) \\ &= \frac{n}{2}(-7(n+1) + 7 + c) \\ &= -7 \cdot \frac{n(n+1)}{2} + \frac{7+c}{2} \cdot n \\ &= -7 \sum_{k=1}^n k + \frac{7+c}{2} \sum_{k=1}^n 1 \\ &= \sum_{k=1}^n \left(-7n + \frac{7+c}{2}\right) \end{aligned}$$

$$\boxed{U_n = -7n + \frac{7+c}{2}}$$

**Part (b)**

Observe that  $U_{n+1} - U_n = -7$ . Hence,  $U_n$  is in arithmetic progression. Thus,  $U_{n+1} = U_n - 7$ , with  $U_1 = \frac{7+c}{2}$ .

$$\boxed{U_{n+1} = U_n - 7, U_1 = \frac{7+c}{2}, n \geq 1}$$

**Problem 14.**

The positive numbers  $x_n$  satisfy the relation

$$x_{n+1} = \sqrt{\frac{9}{2} + \frac{1}{x_n}}$$

for  $n = 1, 2, 3, \dots$

- (a) Given that  $n \rightarrow \infty$ ,  $x_n \rightarrow \theta$ , find the exact value of  $\theta$ .  
 (b) By considering  $x_{n+1}^2 - \theta^2$ , or otherwise, show that if  $x_n > \theta$ , then  $0 < x_{n+1} < \theta$ .

**Solution****Part (a)**

$$\begin{aligned} \theta &= \lim_{n \rightarrow \infty} \sqrt{\frac{9}{2} + \frac{1}{x_n}} \\ &= \sqrt{\frac{9}{2} + \frac{1}{\lim_{n \rightarrow \infty} x_n}} \\ &= \sqrt{\frac{9}{2} + \frac{1}{\theta}} \\ \implies \theta^2 &= \frac{9}{2} + \frac{1}{\theta} \\ \implies 2\theta^3 &= 9\theta + 2 \\ \implies 2\theta^3 - 9\theta - 2 &= 0 \\ \implies (\theta + 2)(2\theta^2 - 4\theta - 1) &= 0 \end{aligned}$$

Hence,  $\theta = -2$  or  $2\theta^2 - 4\theta - 1 = 0$ . We reject  $\theta = -2$  since  $\theta > 0$ . We thus consider  $2\theta^2 - 4\theta - 1 = 0$ . By the quadratic formula,  $\theta = 1 + \sqrt{\frac{3}{2}}$  or  $\theta = 1 - \sqrt{\frac{3}{2}}$ . Once again, we reject  $\theta = 1 - \sqrt{\frac{3}{2}}$  since  $\theta > 0$ . Thus,  $\theta = 1 + \sqrt{\frac{3}{2}}$ .

$$\theta = 1 + \sqrt{\frac{3}{2}}$$

**Part (b)**

Consider  $x_{n+1}^2 = \frac{9}{2} + \frac{1}{x_n}$ . If  $x_n > \theta$ , then  $\frac{1}{x_n} < \frac{1}{\theta}$ . Hence,  $x_{n+1}^2 < \frac{9}{2} + \frac{1}{\theta} = \theta^2$ . Thus,  $0 < x_{n+1} < \theta$ .
