

Problem 1.

The planet Mercury travels around the sun in an elliptical orbit given approximately by

$$r = \frac{3.442 \times 10^7}{1 - 0.206 \cos \theta}$$

where r is measured in miles and the sun is at the pole.

Sketch the orbit and find the distance from Mercury to the sun at the aphelion (the greatest distance from the sun) and at the perihelion (the shortest distance from the sun).

Solution

At the aphelion, r is maximized. Hence, the denominator of r is minimized. Hence, $\cos \theta$ is maximized. Since the maximum value of $\cos \theta$ is 1,

$$\begin{aligned} r &= \frac{3.442 \times 10^7}{1 - 0.206 \cdot 1} \\ &= 4.34 \times 10^7 \text{ (3 s.f.)} \end{aligned}$$

Hence, the distance from Mercury to the sun at the aphelion is 4.34×10^7 miles.

$$\boxed{4.34 \times 10^7 \text{ miles}}$$

At the perihelion, r is minimized. Hence, the denominator of r is maximized. Hence, $\cos \theta$ is minimized. Since the minimum value of $\cos \theta$ is -1 ,

$$\begin{aligned} r &= \frac{3.442 \times 10^7}{1 - 0.206 \cdot -1} \\ &= 2.85 \times 10^7 \text{ (3 s.f.)} \end{aligned}$$

Hence, the distance from Mercury to the sun at the perihelion is 2.85×10^7 miles.

$$\boxed{2.85 \times 10^7 \text{ miles}}$$

Problem 2.

A variable point P has polar coordinates (r, θ) , and fixed points A and B have polar coordinates $(1, 0)$ and $(1, \pi)$ respectively. Given that P moves so that the product $PA \cdot PB = 2$, show that

$$r^2 = \cos 2\theta + \sqrt{3 + \cos^2 2\theta}$$

- (a) Given that $r \geq 0$ and $0 \leq \theta \leq 2\pi$, find the maximum and minimum values of r , and the values of θ at which they occur.
- (b) Verify that the path taken by P is symmetry about the lines $\theta = 0$ and $\theta = \frac{\pi}{2}$, giving your reasons.

Solution

Note that A and B have Cartesian coordinates $(1, 0)$ and $(-1, 0)$ respectively. Let $P(x, y)$. Using the Distance Formula,

$$\begin{aligned} PA^2 &= (x - 1)^2 + y^2 \\ PB^2 &= (x + 1)^2 + y^2 \end{aligned}$$

Since $PA \cdot PB = 2$,

$$\begin{aligned} &PA^2 \cdot PB^2 = 4 \\ \implies &((x - 1)^2 + y^2)((x + 1)^2 + y^2) = 4 \\ \implies &(x - 1)^2(x + 1)^2 + y^2((x - 1)^2 + (x + 1)^2) + y^4 = 4 \\ \implies &(x^2 - 1)^2 + y^2(2x^2 + 2) + y^4 = 4 \\ \implies &x^4 - 2x^2 + 1 + 2x^2y^2 + 2y^2 + y^4 = 4 \\ \implies &(x^4 + 2x^2y^2 + y^4) - 2(x^2 - y^2) = 3 \\ \implies &(x^2 + y^2)^2 - 2(x^2 - y^2) = 3 \end{aligned}$$

Note that

$$\begin{aligned} x^2 - y^2 &= (r \cos \theta)^2 - (r \sin \theta)^2 \\ &= r^2 (\cos^2 \theta - \sin^2 \theta) \\ &= r^2 \cos 2\theta \end{aligned}$$

Hence,

$$\begin{aligned} &(r^2)^2 - 2r^2 \cos 2\theta = 3 \\ \implies &r^2 = \frac{-(-2 \cos 2\theta) \pm \sqrt{(-2 \cos 2\theta)^2 - 4 \cdot 1 \cdot -3}}{2 \cdot 1} \\ &= \cos 2\theta \pm \sqrt{\cos^2 2\theta + 3} \end{aligned}$$

Since $\sqrt{\cos^2 2\theta + 3} > \cos 2\theta$ and $r^2 \geq 0$, we reject the negative case. Thus,

$$r^2 = \cos 2\theta + \sqrt{3 + \cos^2 2\theta}$$

Part (a)

The maximum value of r is achieved when A , B and P are collinear, whence $\theta = 0, \pi$.

$$\begin{aligned} r^2 &= \cos(2 \cdot 0) + \sqrt{3 + \cos^2(2 \cdot 0)} \\ &= 3 \\ \implies r &= \sqrt{3} \end{aligned}$$

The maximum value of r is $\sqrt{3}$ and occurs when $\theta = 0, \pi$.

The minimum value of r is achieved when P is equidistant from A and B , whence $\theta = \frac{1}{2}\pi, \frac{3}{2}\pi$.

$$\begin{aligned} r^2 &= \cos\left(2 \cdot \frac{1}{2}\pi\right) + \sqrt{3 + \cos^2\left(2 \cdot \frac{1}{2}\pi\right)} \\ &= 1 \\ \implies r &= 1 \end{aligned}$$

The minimum value of r is 1 and occurs when $\theta = \frac{1}{2}\pi, \frac{3}{2}\pi$.

Part (b)

$$((x-1)^2 + y^2)((x+1)^2 + y^2) = 4$$

Consider the transformation $y \mapsto -y$.

$$\begin{aligned} &((x-1)^2 + (-y)^2)((x+1)^2 + (-y)^2) = 4 \\ \implies &((x-1)^2 + y^2)((x+1)^2 + y^2) = 4 \end{aligned}$$

Since the path taken by P is invariant under the transformation $y \mapsto -y$, it is symmetric about the x -axis, or the line $\theta = 0$.

Consider the transformation $x \mapsto -x$.

$$\begin{aligned} &((-x-1)^2 + y^2)((-x+1)^2 + y^2) = 4 \\ \implies &((x-1)^2 + y^2)((x+1)^2 + y^2) = 4 \end{aligned}$$

Since the path taken by P is invariant under the transformation $x \mapsto -x$, it is symmetric about the y -axis, or the line $\theta = \frac{\pi}{2}$.

Problem 3.

- (a) Explain why the curve with equation $x^3 + 2xy^2 - a^2y = 0$ where a is a positive constant lies entirely in the region $|x| \leq 2^{-\frac{3}{4}}a$.
- (b) Show that the polar equation of this curve is $r^2 = \frac{a^2 \tan \theta}{2 - \cos^2 \theta}$.
- (c) Sketch the curve.

Solution**Part (a)**

$$\begin{aligned} x^3 + 2xy^2 - a^2y &= 0 \\ \implies 2y^2 - a^2y + x^3 &= 0 \end{aligned}$$

Consider the discriminant $\Delta = (-a^2)^2 - 4 \cdot 2x \cdot x^3 = a^4 - 8x^4$. For points on the curve, $\Delta \geq 0$.

$$\begin{aligned} \Delta &\geq 0 \\ \implies a^4 - 8x^4 &\geq 0 \\ \implies x^4 &\leq 2^{-3}a^4 \\ \implies |x| &\leq 2^{-\frac{3}{4}}a \end{aligned}$$

Part (b)

$$\begin{aligned} x^3 + 2xy^2 - a^2y &= 0 \\ \implies x^3 + 2xy^2 &= a^2y \\ \implies 2x^3 + 2xy^2 - x^3 &= a^2y \\ \implies 2x(x^2 + y^2) - x^3 &= a^2y \\ \implies 2xr^2 - x^3 &= a^2y \\ \implies 2r^2 - x^2 &= a^2 \frac{y}{x} \\ \implies 2r^2 - (r \cos \theta)^2 &= a^2 \tan \theta \\ \implies 2r^2 - r^2 \cos^2 \theta &= a^2 \tan \theta \\ \implies r^2 (2 - \cos^2 \theta) &= a^2 \tan \theta \\ \implies r^2 &= \frac{a^2 \tan \theta}{2 - \cos^2 \theta} \end{aligned}$$

Part (c)

Problem 4.

The curve C has polar equation $r = 1 - \sin 3\theta$, where $0 \leq \theta \leq 2\pi$.

- Sketch the curve C , showing the tangents at the pole and the intersections with the axes.
- Find the gradient of the curve at the point where $\theta = \frac{\pi}{3}$, giving your answer in the form $a + b\sqrt{3}$, where a and b are constants to be determined.

Solution**Part (a)**

Consider $\theta = 0 \implies r = 1 - \sin(3 \cdot 0) = 1$. Thus, C intersects the horizontal axis at $(1, 0)$. By symmetry, C also intersects the horizontal axis at $(1, \pi)$.

Consider $\theta = \frac{\pi}{2} \implies r = 1 - \sin\left(3 \cdot \frac{\pi}{2}\right) = 2$. Thus, C intersects the vertical axis at $\left(2, \frac{\pi}{2}\right)$.

Consider $\theta = \frac{3}{2}\pi \implies r = 1 - \sin\left(3 \cdot \frac{3}{2}\pi\right) = 0$. Thus, C intersects the pole.

For tangents at the pole, $r = 0 \implies \sin 3\theta = 1 \implies 3\theta = \frac{1}{2}\pi, \frac{5}{2}\pi, \frac{9}{2}\pi$. Hence, $\theta = \frac{1}{6}\pi, \frac{5}{6}\pi, \frac{3}{2}\pi$.

Part (b)

Note that

$$\begin{aligned} \left. \frac{dr}{d\theta} \right|_{\theta=\frac{\pi}{3}} &= (-3 \cos 3\theta) \Big|_{\theta=\frac{\pi}{3}} \\ &= -3 \cos \left(3 \cdot \frac{\pi}{3}\right) \\ &= 3 \end{aligned}$$

Observe that when $\theta = \frac{\pi}{3}$, $r = 1 - \sin\left(3 \cdot \frac{\pi}{3}\right) = 1$.

$$\begin{aligned}\left.\frac{dy}{dx}\right|_{\theta=\frac{\pi}{3}} &= \left.\left(\frac{\frac{dr}{d\theta} \sin \theta + r \cos \theta}{\frac{dr}{d\theta} \cos \theta - r \sin \theta}\right)\right|_{\theta=\frac{\pi}{3}} \\&= \frac{3 \cdot \sin \frac{\pi}{3} + 1 \cdot \cos \frac{\pi}{3}}{3 \cdot \cos \frac{\pi}{3} - 1 \cdot \sin \frac{\pi}{3}} \\&= \frac{3 \cdot \frac{\sqrt{3}}{2} + \frac{1}{2}}{3 \cdot \frac{1}{2} - \frac{\sqrt{3}}{2}} \\&= \frac{3\sqrt{3} + 1}{3 - \sqrt{3}} \\&= \frac{(3\sqrt{3} + 1)(3 + \sqrt{3})}{(3 - \sqrt{3})(3 + \sqrt{3})} \\&= \frac{9\sqrt{3} + 3 + 9 + \sqrt{3}}{9 - 3} \\&= \frac{12 + 10\sqrt{3}}{6} \\&= 2 + \frac{5}{3}\sqrt{3}\end{aligned}$$

When $\theta = \frac{\pi}{3}$, the gradient of the curve is $\left(2 + \frac{5}{3}\sqrt{3}\right)$.
