# Problem 1.

By considering the graphs of  $y = \cos x$  and  $y = -\frac{1}{4}x$ , or otherwise, show that the equation  $x + 4\cos x = 0$  has one negative root and two positive roots.

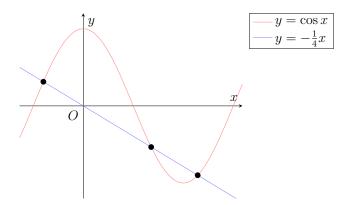

Use linear interpolation, once only, on the interval [-1.5, 1] to find an approximation to the negative root of the equation  $x + 4\cos x = 0$  correct to 2 decimal places.

The diagram shows part of the graph of  $y = x + 4\cos x$  near the larger positive root,  $\alpha$ , of the equation  $x + 4\cos x = 0$ . Explain why, when using the Newton-Raphson method to find  $\alpha$ , an initial approximation which is smaller than  $\alpha$  may not be satisfactory.

Use the Newton-Raphson method to find  $\alpha$  correct to 2 significant figures. You should demonstrate that your answer has the required accuracy.

## Solution

Note that  $x + 4\cos x = 0 \implies \cos x = -\frac{1}{4}x$ . Plotting the graphs of  $y = \cos x$  and  $y = -\frac{1}{4}x$ , we see that there is one negative root and two positive roots. Hence, the equation  $x + 4\cos x = 0$  has one negative root and two positive roots.

Let  $f(x) = x + 4\cos x$ . Let  $\beta$  be the negative root of the equation f(x) = 0. Using linear interpolation on the interval [-1.5, -1],

$$\beta = \frac{-1.5f(-1) - (-1)f(-1.5)}{f(-1) - f(1.5)}$$
$$= -1.24 \text{ (2 d.p.)}$$

$$\beta = -1.24 \; (2 \; \text{d.p.})$$

There is a minimum at x = m such that m is between the two positive roots. Hence, when using the Newton-Raphson method, an initial approximation which is smaller than m would result in subsequent approximations being further away from the desired root  $\alpha$ . Hence, an initial approximation that is smaller than  $\alpha$  may not be satisfactory.

We know from the above graph that  $\alpha \in (\pi, \frac{3}{2}\pi)$ . Following the above discussion, we pick  $\frac{3}{2}\pi$  as our initial approximation.

$$x_1 = \frac{3}{2}\pi$$

$$\Rightarrow x_2 = x_1 - \frac{f(x_1)}{f'(x_1)} = 3.7699$$

$$\Rightarrow x_3 = x_2 - \frac{f(x_2)}{f'(x_2)} = 3.6106$$

$$\Rightarrow x_4 = x_3 - \frac{f(x_3)}{f'(x_3)} = 3.5955$$

$$\Rightarrow x_5 = x_4 - \frac{f(x_4)}{f'(x_4)} = 3.5953$$

Since f(3.55) = -0.1 < 0 and f(3.65) = 0.2 > 0,  $\alpha \in (3.55, 3.65)$ . Hence,  $\alpha = 3.6$  (2 s.f.).

$$\alpha = 3.6 \ (2 \text{ s.f.})$$

# Problem 2.

Find the coordinates of the stationary points on the graph  $y = x^3 + x^2$ . Sketch the graph and hence write down the set of values of the constant k for which the equation  $x^3 + x^2 = k$  has three distinct real roots.

The positive root of the equation  $x^3 + x^2 = 0.1$  is denoted by  $\alpha$ .

- (a) Find a first approximation to  $\alpha$  by linear interpolation on the interval  $0 \le x \le 1$ .
- (b) With the aid of a suitable figure, indicate why, in this case, linear interpolation does not give a good approximation to  $\alpha$ .
- (c) Find an alternative first approximation to  $\alpha$  by using the fact that if x is small then  $x^3$  is negligible when compared to  $x^2$ .

### Solution

For stationary points, y' = 0.

$$y' = 0$$

$$\implies 3x^2 + 2x = 0$$

$$\implies x(3x + 2) = 0$$

Hence, x = 0 or  $x = -\frac{2}{3}$ . When x = 0, y = 0. When  $x = -\frac{2}{3}$ ,  $y = \frac{4}{27}$ . Thus, the coordinates of the stationary points of  $y = x^3 + x^2$  are (0,0) and  $\left(-\frac{2}{3}, \frac{4}{27}\right)$ .

$$\left(-\frac{2}{3}, \frac{4}{27}\right)$$

$$y$$

$$y$$

0

Therefore,  $k \in \left(0, \frac{4}{27}\right)$ .

$$\{k \in \mathbb{R} \colon 0 < k < \frac{4}{27}\}$$

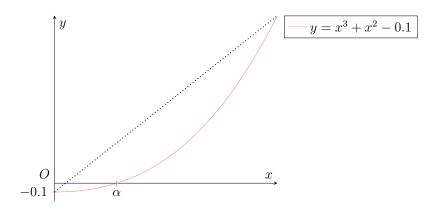

### Part (a)

Let  $f(x) = x^2 + x^2 - 0.1$ . Using linear interpolation on the interval [0, 1],

$$\alpha = \frac{0f(1) - 1f(0)}{f(1) - f(0)}$$
$$= \frac{1}{20}$$

$$\alpha = \frac{1}{20}$$

## Part (b)

On the interval [0,1], the gradient of  $y=x^3+x^2-0.1$  changes considerably. Hence, linear interpolation gives an approximation much less than the actual value.

### Part (c)

For small x,  $x^3$  is negligible when compared to  $x^2$ . Consider  $g(x) = x^2 - 0.1$ . Then the positive root of g(x) = 0 is approximately  $\alpha$ . Hence, an alternative approximation to  $\alpha$  is  $\sqrt{0.1} = 0.316$  (3 s.f.).

$$\alpha = 0.316 \; (3 \; \text{s.f.})$$

# Problem 3.

The equation  $2\cos x - x = 0$  has a root  $\alpha$  in the interval [1, 1.2]. Iterations of the form  $x_{n+1} = F(x_n)$  are based on each of the following rearrangements of the equation:

(a) 
$$x = 2\cos x$$

(b) 
$$x = \cos x + \frac{1}{2}x$$

(c) 
$$x = \frac{2}{3}(\cos x + x)$$

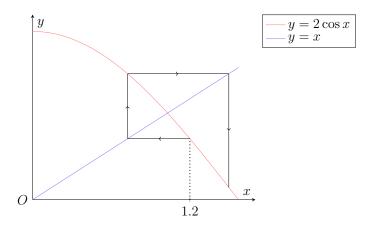

Determine which iteration will converge to  $\alpha$  and illustrate your answer by a 'staircase' or 'cobweb' diagram. Use the most appropriate iteration with  $x_1 = 1$ , to find  $\alpha$  to 4 significant figures. You should demonstrate that your answer has the required accuracy.

#### Solution

### Part (a)

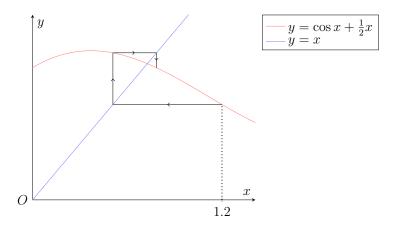

Consider  $f(x) = 2\cos x$ . Then  $f'(x) = -2\sin x$ .

Observe that  $\sin x$  is increasing on [1, 1.2]. Since  $\sin 1 > \frac{1}{2}$ , |f'(x)| > 1 for all  $x \in [1, 1.2]$ . Thus, fixed-point iteration fails and will not converge to  $\alpha$ .

### Part (b)

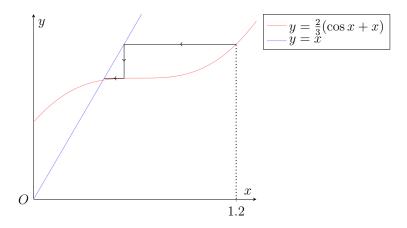

Consider  $f(x) = \cos x + \frac{1}{2}x$ . Then  $f'(x) = -\sin x + \frac{1}{2} - \left(\sin x - \frac{1}{2}\right)$ . Since  $0 \le \sin x \le 1$  for  $x \in \left[0, \frac{\pi}{2}\right]$ , and  $[1, 1.2] \subset \left[0, \frac{\pi}{2}\right]$ , we know  $-\frac{1}{2} \le \sin x - \frac{1}{2} \le \frac{1}{2}$  for  $x \in [1, 1.2]$ . Thus,  $0 \le \left|\sin x - \frac{1}{2}\right| \le \frac{1}{2}$  for  $x \in [1, 1.2]$ . Hence, fixed-point iteration will work and converge to  $\alpha$ .

## Part (c)

Consider  $f(x) = \frac{2}{3}(\cos x + x)$ . Then  $f'(x) = \frac{2}{3}(-\sin x + 1)$ .

For fixed-point iteration to converge to  $\alpha$ , we need |f'(x)| < 1 for x near  $\alpha$ . It thus suffices to show that  $|-\sin x + 1| < \frac{3}{2}$  for all  $x \in [1, 1.2]$ . Observe that  $1 - \sin x$  is strictly decreasing and positive for  $x \in \left[0, \frac{\pi}{2}\right]$ . Since  $1 - \sin 1 < \frac{3}{2}$ , and  $[1, 1.2] \subset \left[0, \frac{\pi}{2}\right]$ , we have that  $|-\sin x + 1| < \frac{3}{2}$  for all  $x \in [1, 1.2]$ . Thus, |f'(x)| < 1 for x near  $\alpha$ . Hence, fixed-point iteration will work and converge to  $\alpha$ .

For  $x \in [1, 1.2]$ ,  $\left| \frac{2}{3} (-\sin x + 1) \right| < \left| -\sin x + \frac{1}{2} \right| < 1$ . Thus,  $x_{n+1} = \frac{2}{3} (\cos x_n + x_n)$  is the most suitable iteration as it will converge to  $\alpha$  the quickest. Using  $F(x) = \frac{2}{3} (\cos x + x)$  with  $x_1 = 1$ ,

$$x_1 = 1$$

$$\Rightarrow x_2 = F(x_1) = 1.02687$$

$$\Rightarrow x_3 = F(x_2) = 1.02958$$

$$\Rightarrow x_4 = F(x_3) = 1.02984$$

$$\Rightarrow x_5 = F(x_4) = 1.02986$$

Since F(1.0295) > 1.0295 and F(1.0305) < 1.0305,  $\alpha \in (1.0295, 1.0305)$ . Hence,  $\alpha = 1.030$  (4 s.f.).

 $\alpha = 1.030 \text{ (4 s.f.)}$
